The present invention generally relates to the field of fiber optics, and, more specifically, to making and using optical fiber and other photonic components. Fiber optics are increasingly used to transmit light energy in numerous applications, such as data transmission and communication. In such applications, a single optical fiber can be used to carry optical signals to numerous receiving points. The optical fiber is typically inserted into the receiving points via a fiber optic connector. To remove the optical fiber from an optical fiber connector, it is often desirable to break the optical fiber, for example, when a replacement fiber is required. Conventionally, the optical fiber is broken using a mechanical force applied to the end of the optical fiber. The disadvantage of this method is that the optical fiber cannot be split evenly, or if the end is rounded, unevenly, without damaging the fiber optic connector. It is desirable to split an optical fiber evenly and, if the end is rounded, to distribute the damage evenly. Using two or more conventional blades can be effective to separate the optical fiber. However, it can be difficult to apply an even uniform force to each of the blades, which can cause uneven or incomplete separation. The uneven splitting of the optical fiber can result in a non-uniform split of the optical fiber, which can interfere with optical signals traveling through the optical fiber. In one aspect, the invention includes a system for cleaving an optical fiber that can uniformly, and with or without rounding of the end of the optical fiber, mechanically cleave the optical fiber. The optical fiber is secured between a first force applying tool and a second force applying tool. The first and second force applying tools have a first force on one side and a second force on the other side. The first force is applied to the first side of the optical fiber. The second force is applied to the second side of the optical fiber. The system, with or without a mechanical cleaving device, breaks the optical fiber at a uniform location. In another aspect, the
